BREAKAWAY LACING FOR EMERGENCY EVACUATION SLIDE

This application claims priority of U.S. Provisional Application Serial No.
5 60/418,838, filed 10/15/2002.

BACKGROUND OF THE INVENTION

This invention relates to emergency evacuation equipment for aircraft, in particular, to inflatable aircraft emergency evacuation slides.

The conventional method of quickly evacuating a large number of passengers from an
10 aircraft in an emergency is to provide multiple emergency exits, each of which is equipped
with an inflatable evacuation slide. These inflatable evacuation slides are normally stored in
an uninflated condition in a container, or slide pack, requiring a minimum of space in the
interior of the aircraft. The slide pack is typically attached to a packboard mounted on or
adjacent to the interior of the aircraft exit door. In a conventional aircraft evacuation slide
15 system, the operation of which is described among other places in United States Patent No.
4,441,582 to Ward, if the aircraft exit door is opened in the "armed" condition, the entire slide
pack to falls to the sill of the aircraft. As the door is moved further away from the doorway
the slide pack falls out of the doorway toward the ground. As the slide pack falls toward the
ground, a lanyard is tensioned to withdraw a pin from the key loop of a series of interlaced
20 loops commonly referred to as "daisy chain" lacing. Withdrawal of the pin from the key loop
of the daisy chain lacing causes the lacing to unravel releasing the slide from the slide pack
for inflation.

Prior art methods of storing a fold uninflated evacuation slide within a pack closed by
conventional daisy chains lacing have proved adequate for small to moderate sized inflation

slides. Conventional daisy chain lacing, however, does not reliably release under the strain of large, tight slide packs or slides that have been stored for a protracted period of time. Accordingly, what is needed is a method of lacing an aircraft evacuation slide that reliably releases under all conditions.

5 SUMMARY OF THE INVENTION

The present invention is directed to a method of lacing together two parts of an inflatable evacuation slide in which a single piece of cord is passed through multiple pairs of apertures or grommets formed in the two parts to be joined. Thereafter, the loops formed by passing the cord through the multiple grommets are laced together and secured with a
10 conventional key loop. In operation, once the key loop is released, since the lacing is composed of a single length of cord, rather than multiple independent loops, the tension in all of the lacing is released simultaneously thereby allowing the lacing to unravel reliably irrespective of the tension on the lacing or the duration of its storage prior to being released.

15 BRIEF DESCRIPTION OF THE DRAWING

The present invention will be better understood from a reading of the following detailed description, taken in conjunction with the accompanying drawing figures in which like references designate like elements and, in which:

FIG. 1 is a side view of an evacuation slide incorporating features of the present
20 invention;

FIG. 2 is a side view of an evacuation slide pack, portions of which are joined together by lacing incorporating features of the present invention;

FIG. 3 is a partial perspective view of two portions of an evacuation slide joined by prior art daisy chain lacing;

FIG. 4 is a partial perspective view of two portions of an evacuation slide joined by prior art lacing;

5 FIG. 5 is a partial perspective view of two portions of an aircraft evacuation slide joined together by lacing incorporating features of the present invention;

FIG. 6 is an enlarged perspective view of a portion of the lacing shown in FIG. 5;

FIG. 7 is a cross-sectional illustration of two parts of an aircraft evacuation slide joined together by lacing incorporating features of the present invention;

10 FIG. 8 is a cross-section of two portions of an aircraft evacuation slide joined by an alternative embodiment of lacing incorporating features of the present invention;

FIG. 9 is a cross-section of two portions of an aircraft evacuation slide joined by an alternative embodiment of lacing incorporating features of the present invention;

15 FIG. 10 is a perspective view of an aircraft evacuation slide including a toe end compartment joined together by lacing incorporating features of the present invention; and

FIG. 11 is a partial perspective view of an alternative hybrid lacing incorporating features of the present invention.

DETAILED DESCRIPTION

20 The drawing figures are intended to illustrate the general manner of construction and are not necessarily to scale. In the detailed description and in the drawing figures, specific illustrative examples are shown and herein described in detailed. It should be understood, however, that the drawing figures and the detailed description are not intended

to limit the invention to the particular form disclosed, but are merely illustrative and intended to teach one of ordinary skill how to make and/or use the invention claimed herein and for setting forth the best mode for carrying out the invention.

With reference to FIGs. 1 and 2, an inflatable evacuation slide assembly 10
5 generally comprises a head end 12 and a foot end 14. Head end 12 is configured to couple evacuation slide assembly 10 to an exit door 18 of an aircraft 20, while foot end 14 is in contact with the ground 22 such that the slide assembly 10 provides a sloping surface to permit the rapid egress from passengers from aircraft 20. The entire inflatable evacuation slide assembly 10 is preferably fabricated from an air impervious material such as a
10 lightweight fabric that has been coated with an elastomer such as rubber or urethane. The various parts of the inflatable evacuation slide assembly 10 may be joined together with a suitable adhesive whereby the structure will form a unitary composite structure capable of maintaining its shape during operation. The entire structure of the inflatable evacuation slide assembly 10 is preferably formed such that all the chambers comprising the structure
15 are interconnected pneumatically, such that a single pressurized gas source, such as compressed carbon-dioxide, nitrogen, or argon, output from a pyrotechnic gas generator, or a hybrid pyrotechnic/compressed gas generator may be utilized for its deployment.

As shown in FIG. 2, evacuation slide assembly 10 is typically stored in a folded, uninflated condition within a slide pack 24 mounted to the interior surface 16 of aircraft
20 door 18. As the aircraft door is opened in the armed condition, the girt portion 26 of evacuation slide assembly 10, which is secured to the aircraft door ^{Sill} ~~seal~~ by girt bar 28, pulls ^{pull} slide pack 24 off its mountings on interior surface 16 of door 18. This allows slide pack 24 to begin to fall. After slide pack 24 has fallen a predetermined distance, a lanyard 30

*pull
18SEP03
09-22-03*

attached to girt 26 withdraws a pin 32 from a key loop 34 which allows the lacing 36 to unravel thereby releasing the evacuation slide assembly 10 from the enclosure of slide pack 24.

With reference to FIGs. 3 and 4, a prior art "daisy chain" lacing for joining two parts of an inflatable aircraft evacuation slide comprises a plurality of fixed loops 38 and key loops 40 fastened to one end of a panel 44. A like number of apertures 42 are formed in the opposite end of a panel 46 to be joined to panel 44. The ends of panels 44 and 46 are lined up so that each of apertures 42 are positioned over one of loops 38 and 40. Each of the loops 38, 40 are passed through apertures 42 in panel 46. Beginning with the loop furthest from key loop 40 at each end, each loop is threaded through the adjacent outboard loop working inwardly toward key loops 40. Key loops 40 are then held together by threading one through the other and then passing a pin 52 attached to a lanyard 54 through the resulting loop. Although there are numerous ways of securing the key loop of such a laced assembly, the basic principal of a plurality of individual loops threaded one through another is consistent throughout all prior art evacuation slide daisy chain style lacing.

FIG. 5 is a perspective view of two parts of an inflatable aircraft evacuation slide joined together by means of lacing incorporating features of the present invention. As shown in FIG. 5, a first panel 58 has formed therein a plurality of apertures 62, which in a preferred embodiment are provided with suitable grommets for reinforcement. A second panel 60 has a plurality of corresponding apertures 64 formed therein. (As used herein "corresponding apertures" means that the apertures in second panel 60 will line up with apertures 62 in first panel 58 to facilitate lacing the assembly together.) A length of cord 66 is fastened by suitable means (e.g., stitching) at one end 68 to second panel 60 and at a

second end 74 to second panel 60. A key loop 76 is formed by fastening a portion of cord 66 together with stitching 50 proximal second end 74. Cord 66 may be any suitable length of cord made from natural or synthetic fibers, however, in the illustrative embodiment cord 66 is MIL-C-7515 nylon cord.

5 With reference to FIG. 6, portions of cord 66 are threaded through apertures 64 of panel 60 to form a series of substantially equal size loops 78 (hereinafter referred to alternatively as "loops" or "breakaway loops") and a substantially equally sized terminal loop 80. Key loop 76 is also passed through one of apertures 64.

 As shown in FIG. 7, each of loops 78 is threaded through apertures 62 of panel 58
10 and thereafter threaded through an adjacent loop 78 to form a chain of interlocked loops terminating in a terminal loop 80 through which is threaded key loop 76. Alternatively, in lieu of anchoring terminal loop 80 to key loop 76, terminal loop 80 could be anchored directly to panel 58 or 60 (e.g., by passing terminal loop 80 through a grommet and securing with a pin, passing terminal loop 80 through a cord cutter anchored to panel 58 or
15 other conventional means) all within the scope of the present invention. Also, in lieu of using stitching 50, key loop 76 may be formed by tying a knot in cord 66 proximal end 74.

 With reference to FIGs. 8, 9 and 10, according to another embodiment of the present invention, a bi-directional lacing in accordance with the present invention is used to close a compartment 98 at the foot end 14 of an evacuation slide assembly 10. In the
20 embodiment of FIGs. 8 and 9, cord 106 and cord 112 are threaded through a plurality of apertures 102 and 104 in panels 108 and 110 to form a series of loops 114 and 116 as well as key loops 118 and 120 (which, as noted hereinbefore, may be stitched or knotted). Key loops 118 and 120 are threaded through each other and secured with a pin 90 attached to a

lanyard 92. Alternatively, as shown in FIG. 9, ping 90 is replaced with a pyrotechnic cord cutter 122. In operation, under the appropriate conditions, as the evacuation slide assembly 10 is deployed, a signal is sent to pyrotechnic cord cutter 122 which severs both of key loops 118 and 120. Because cord 106 and cord 112 form all of the breakaway loops that
5 form the breakaway lacing, once the key loops 118 and 120 are released the tension in the lacing is relieved simultaneously and uniformly rather than seriatim as in the prior art daisy chain lacing. Accordingly, the friction between each of the interlocking loops is relieved uniformly and the lacing unravels immediately and more reliably than has been heretofore possible.

10 With reference to FIG. 11, yet another alternative embodiment of a hybrid lacing comprising a combination of daisy chain loops and breakaway loops is shown. In the embodiment of FIG. 11, a plurality of conventional daisy chain loops 140 are threaded through corresponding apertures 142 in a panel 144 beginning at the outermost ends and working inward toward the center. The innermost of daisy chain loops 140 are then laced
15 to the outermost of a plurality of breakaway loops 146, which thereafter are threaded together as hereinbefore described. The innermost of breakaway loops 146 are secured to key loops 148 and 150. Key loops 148 and 150 are then secured by pins 152 and 154 connected to a common lanyard 156. A master loop 160 redundantly secures key loops 148 and 150 together. The purpose of master loop 160 is to prevent accidental unraveling
20 of the lacing in the event pins 152 and 154 are inadvertently withdrawn. In normal operation, master loop 160 is severed by means of a pyrotechnic cord cutter THAT "arms" the lacing such that withdrawal of pins 152 and 154 will cause the lacing to unravel. Once

the slide is in position for deployment pins 152 and 154 are withdrawn by means of common lanyard 156 which causes the breakaway lacing to unravel.

Although certain illustrative embodiments and methods have been disclosed herein, it will be apparent from the foregoing disclosure to those skilled in the art that variations
5 and modifications of such embodiments and methods may be made without departing from the spirit and scope of the invention. For example, a myriad of methods for securing the key loop of the breakaway lacing in accordance with the present invention are possible. Accordingly, it is intended that the invention shall be limited only to the extent require by the appended claims and the rules and principles of applicable law.
